

I audited a global central-bank ranking.

The biggest finding was not the ranking.

It was the data problem behind it.

4,298 rows ≠ 10 central banks

A business-analysis case study in data provenance, market research, and executive storytelling.

MBA • B.COM • BUSINESS ANALYSIS • RESEARCH

What I found, what the data actually says, and how I would rebuild the product correctly.

The model looked analytical. The scores were hardcoded.

A visual can be polished and still fail the most basic traceability test.

SOURCE CODE / fetch_authentic_data.py

“reproduce the user's requested baseline rankings”

```
...
'SNB': [29.4, 18.0, 16.5, 12.5, 13.0],
'FED': [25.2, 18.5, 15.0, 12.0, 14.5],
...
}
df.to_csv('authentic_cbc_i_scores.csv')
```

This is circular logic: the desired output became the input.

WHAT THE CSV ACTUALLY CONTAINS

- 1 market series
US 10Y Treasury yield
- 0 country panels
No cross-bank coverage
- 0 inflation series
No mandate data
- 0 policy statements
No NLP evidence
- 0 FX series
No currency evidence

BA lesson: validate the data lineage before debating the dashboard.

Evidence: project source code and local CSV audit. No cross-country ranking is used in this carousel.

Five questions turn an attractive model into a defensible decision product.

05 VALUE Does the output change an action? Impact

If one answer is “no,” the ranking is not ready for executive use.

What 4,298 rows can - and cannot - answer.

The FRED file is clean enough for Treasury analysis, but insufficient for a global credibility index.

4,298

weekday rows

4,120

valid observations

178

holiday nulls

0

duplicate dates

THE FILE CAN ANSWER

- ✓ How US 10-year yields changed over time
- ✓ When volatility and repricing were most extreme
- ✓ Whether the current yield level is historically unusual

THE FILE CANNOT ANSWER

- ✗ Which central bank is most credible
- ✗ Whether words matched policy actions
- ✗ How inflation, forecasts, bonds, and FX compare globally

Scope correction

Reframe the current output as a US Treasury market-risk dashboard - not a global central-bank leaderboard.

The actual data tells a U-shaped market story.

Annual average US 10-year Treasury yield, calculated from valid daily observations.

0.52%

sample low

4 Aug 2020

4.98%

sample peak

19 Oct 2023

4.50%

latest yield

23 Jun 2026

The post-2020 move was a structural repricing, not a short-lived spike.

Source: FRED DGS10 CSV in the project repository. Y-axis is percentage points.

High yield does not mean market panic.

The most decision-useful insight appears only when level and volatility are separated.

YIELD LEVEL

97th

historical percentile

Latest yield: 4.50%

21-DAY VOLATILITY

39th

historical percentile

Latest annualized reading: 67 bp

SO WHAT?

The market is pricing a high-rate regime...

...without behaving like a current crisis.

This distinction matters for risk, duration, and scenario design.

Insight > chart

Percentiles calculated across the full 2010-2026 valid-observation history.

One institution × five pillars × one consistent time axis - repeated across all ten banks.

Only after coverage, definitions, and time windows match should the model produce a leaderboard.

A business analyst connects data requirements, model controls, stakeholders, and adoption.

Compare institutions with consistent definitions

Make every score traceable and auditable
